Paper ID	71
Paper Title	Annotation Reliability of Manglish Sentiment Resources: A Review of Labelling Practices and Evidence

Reviewer #1

Questions

1. Relevant to the scope of the conference
Moderately Relevant

2. Abstract Does the abstract is clearly and accurately describes the content of the paper?
Good

3. Originality & Novelty Does the paper present a novel AI method, framework, application, or significant improvement over existing approaches?
Neutral

4. Methodological Rigor Are the research design and methods robust, appropriate, and clearly explained?
Poor

5. Data Analysis & Results Are the results accurate, reproducible, properly analysed, and supported by suitable comparisons, validation, or statistical evidence?
Neutral

6. Discussion & Conclusion Are the findings critically interpreted and supported by the results?
Neutral

7. Real-World Impact & AI Applications Does the study demonstrate meaningful potential or practical value in addressing real-world problems through AI?
Good

8. Clarity & Presentation Is the manuscript well-organised, clearly written in academic English, logically structured, and well-presented?
Good

9. References & Relevance Is the literature current, relevant, sufficiently comprehensive, and properly formatted according to the conference guidelines?
Good

10. Please state reviews for the authors to improve the content of the paper.
The paper reviews an important issue in Malay-English sentiment analysis: the reliability of dataset labels. The manuscript is generally well organised and the discussion explains why agreement between annotators does not always mean that the labels are correct. However, the following points need revision:

1. Please identify the review type and provide the full search strings, search dates, and numbers of studies found, screened and selected. Explain how information was extracted and synthesised.

2. Please justify the choice of 10,000 messages as the dataset size threshold and 50% as the threshold for class dominance.

3. Please correct the inconsistency in Table 3. MY-EN-CS is marked as not dominated by one label, although its largest class is 52% which exceeds the stated threshold.

4. Please distinguish subjectivity annotation from sentiment polarity annotation. Explain how binary subjectivity labels are compared with positive, negative and neutral sentiment labels.

5. Please distinguish annotation consistency from label correctness. An agreement coefficient supports consistency, but independent validation is needed to assess correctness.

6. Please explain why the sporting-result example should be positive rather than neutral. A positive event does not always express a positive opinion. Relate the judgement to the annotation guidelines.

7. Please clarify the calculation of the neutral proportion before and after removing the 512 posts. Distinguish individual tool votes from final majority labels.

8. Please explain the contribution beyond earlier reviews and add a limitations paragraph. Missing agreement evidence does not prove that a dataset is unreliable.

9. Please correct minor language errors and repeated sentences. For example, change “generative” to “generative models” in the abstract. Also complete or remove the template publication details.

Good

10. Please state reviews for the authors to improve the content of the paper.

The paper addresses a relevant topic on the reliability of sentiment annotation for Manglish data and provides a useful discussion of linguistic challenges, annotation approaches, class imbalance, and inter-annotator agreement. The manuscript is generally clear and supported by relevant literature.

The main improvement needed is in the review methodology. This is a review paper so the authors should briefly clarify the literature search and selection process, including the databases used, the main search terms, the number of studies finally included, and how the selected papers were screened. This will make the review more transparent and easier to follow.

The authors should also provide stronger justification for the four criteria used to compare the datasets, especially the 10,000-message threshold and the definition of class dominance. These should be presented as criteria adopted for this review rather than universal quality standards.

In addition, the paper would benefit from a clearer distinction between annotation reliability and annotation correctness. High agreement does not necessarily mean that the labels are correct, particularly when multiple automatic tools may share similar limitations.

The discussion on neutral sentiment could also be clarified by distinguishing genuinely neutral cases from ambiguous, mixed, or incorrectly detected sentiment.

Overall, the paper has a meaningful contribution and is suitable for the conference after addressing these key revisions.
